Endothelial Function of Adolescents with History of Premature Coronary Artery Disease In One Parent

Author: Yalda Kiani

Superviser:Dr Mohammad Hashemi (Assistant Professor)

Abstract

Background: In young adults, a family history of premature coronary artery disease (CAD) as well as genetic and environmental factors are independent risk factors for coronary artery disease

Methods: Endothelial function in 30 children of patients with documented CAD (men ≤ 45 years, women ≤ 50 years) was studied (21 boy, 9 girl; mean age, 14.9 +/- 2.3 years). Chidren did not have diabetes mellitus, dyslipidemia, hypertension, and were nonsmokers (active/passive). We used vascular ultrasound ,and measured resting Basal Brachial artery Diameter(BBD) ,Endothelium-Dependent Dilatation(EDD) in response to increased flow and to sublingual glyceryltrinitrate (GTN), an Endothelium-Independent Dilator(EID). These parameters were also measured in 30 control subjects with normal parents(18 boy,12 girl ;mean age,14.2 +/- 2years)and results were compared with each other.

Results: Adolescents in CAD group had abnormal Endothelial Dependent Dilatation or EDD/BBD(8.5 +/- 3.4% vs 11.8 +/- 4.5% in control subjects; P= 0.003).Endothelial Independent Dilation(EID/BBD) in the fimily history group was significantly more than control subjects (18.5 +/- 6.7% vs 11.9 +/- 5.2%; P <0.001). EDD/EID or the index of endothelial function was significantly lower in the family history group (0.92 +/- 0.05 vs 1+/- 0.03 ;P<0.001).There was no difference in EDD/EID index between those with history of premature CAD in mother (7 cases) or premature CAD in father(23 cases);(0.92 +/- 0.04 vs 0.91+/- 0.05).

Conclusions : Normal adolescents without any cardiovascular risk factors but premature coronary artery disease in one parent may have endothelial dysfunction, and there is no difference whether mother has CAD or father.

KEY Words : Endothelial dependent dilation; family history;CAD risk factors; premature coronary artery disease

Introduction

Atherosclerosis is a diffuse process of the arterial tree that starts in childhood and early adult life .(1) Its preclinical stage may last for decades, during which time atherosclerotic changes progress slowly, eventually causing lumenal stenosis .(2,3)It has been well known for several decades that subjects with a family history of myocardial infarction are at a higher risk of developing coronary artery disease .(4-7) Several studies showed that risk of coronary disease death in the first-degree relatives of coronary patients increases 2.5- to 7-fold in comparison to those without this background.(8)

The key early event in atherogenesis is Endothelial dysfunction,(2,3) and early marker of endothelial dysfunction is the loss of Endothelial Dependen Dilatation , thought to be related to reduced activity of NO.(9,10)This substance can not only induce vasodilation but also possesses antitrophic properties.(11,12) One of noninvasive tests for studing of endothelial function based on ultrasound measures flow-mediated changes in arterial diameter in relatively superficial arteries, such as the brachial arteries.(13) This method correlates significantly with invasive testing of coronary endothelial function (13,14), as well as with the severity and extent of coronary atherosclerosis (15).

In this study, we have evaluated a cohort of adolescents with history of premature CAD in one parent but in whom the potentially confounding risk factors

were excluded to examine only the influence of family history on endothelial function.

Materials and Methods

36 patients (27 men ≤ 45 years,9 women ≤ 50 years) with premature CAD (angiographically documented ≥ 75 % stenosis of at least one epicardial coronary artery, or admission in CCU because of ST elevation/Q waves MI on surface ECG plus adequate rising of cardiac enzymes) were selected from angiography records and coronary care units of two Isfahan hospitals, over a 9-month period. By using a questionnaire contained smoking history,hypertension ,diabetes mellitus, dyslipidemia and family history of premature CAD, we assessed these cardiovascular risk factors in CAD patients. To exclude CAD in their spouse, they were questioned about history of chest pain , if they had never experienced chest pain they examined with resting ECG and if it was completely normal their 10-18 years old children entered the study.

In the control group ,both parents were asked about cardiovascular risk factors with the same questionnaire, if both of them had never chest pain and their resting ECG was free from any abnormalities their 10-18 years old children were studied as control group.

The young adults in both family history and control groups were asked about history of lifelong smoking or passive smoking (history of current smoking in one parent at home)and if the response was positive the child was excluded from our study (N=0 subject). After at least 5 minutes resting we measured supine BP in all adolescents and if resting BP<130/85 ,rest of study continued.(N=2 subjects in the

case group were excluded because of their BP>130/85). Biochemical tests from venous blood samples were evaluated in 64 subjects (CAD and control groups) after a 12-hour overnight fasting for plasma glucose (Pars Azmoun kit;2003),total cholesterol(Pars Azmoun kit;2003),LDL cholesterol(Randox kit),and triglycerides(Pars Azmoun kit;2003). In this study HDL cholesterol, lipoprotein(a), fibrinogen and homocysteine levels were not measured. Those young adults with, FBS >110mg/dl , Total Cholesterol >240mg/dl , LDL cholesterol >160mg/dl , and Triglyceride >250mg/dl were excluded from study ;(N=4 subjects in the family history group because of their abnormal lipid profile but none in control group).

Brachial artery evaluation

We studied endothelial function of brachial artery by using a 7.5-MHz linear array transducer B-mode ultrasound (Dornier Ultrasoud system 1992) in supervise of an expert sonographist who was unaware of study subjects(similar method to previous studies).(2) After resing for at least 10 minutes brachial artery was imaged in a longitudinal section 5 to 7cm above the elbow.To measure the diameter of artery the best view of the anterior and posterior wall layers was needed .Finding the best position of transducer to show brachial artery , we marked best point on the skin and the arm did not move after that throughout study and depth and gain settings of maschine were the same during study. After measurement of Basal brachial artery (BBD);to study Endothelium Dependent Dilatation, flow to brachial artery was increased by aid of pneumatic tourniquet distal to brachial artery around forearm and inflated to 250-300 mm Hg for 4.5 minutes .Second scan of brachial artery was imaged 60 & 90 seconds after releasing cuff and brachial artery diameter was measured(EDD).Then we waited for 10 to 15 minutes to vessel returned to its baseline

status;again brachial artery diameter (EID) was recorded,but this time after passing 3 to 4 minutes priod of administeration one puff (400 microgram)of sublingual GTN spray (Pohl-Boskamp Gmbl & Co-Germany) .The amount of increased diameter of Brachial artery in two situations (EDD & EID)were compared with resting diameter (BBD) as percent measurements.(100 %)The relation of two situations (EDD & EID) were compared to each other (EDD / EID).

Results

The spss software was used for the data entry and analysis. We showed variables as mean ± SD. Two sample t- test was used to compaire the data in CAD and control.In two family history subgroups means those whose fathers had premature CAD ,and those whose mothers had disease, we used one-way ANOVA to compare EDD/BBD , EID/BBD responses and EDD/EID index. The relationship between age and Basal Brachial artery Diameter(BBD), EDD/BBD ,EID/BBD and EDD/EID index was studied by univariate and multivariate regression analysis Statistical significancein our study was P-value< 0.05..

23 men and 7 women (total 30 patients) were selected as CAD group;28 subjects with angiographically establishrd CAD and only 2 from coronary care unit.All of 30 control parents were selected as previously described in materials and methods.The coronary risk factors (DM, HTN, dyslipidemia, smoking, and family history of premature CAD) in the parents are as followes: In the control group 96.7% of mothers were free from all risk factors but in the subgroup ;mothers with premature CAD ,100% of mothers had more than one risk factor. (P<0.001).In the control group 80% of fathers did not have any coronary risk factors but in the subgroup ;fathers with

premature CAD , 91.3% had at least one risk factor. (P<0.001)The most prevalent risk factor in this subgroup was dyslipidemia(73.2%).

Demographic Characteristics of Family History and Control Young Adults:

There was no significant difference in age of young adults in CAD and control groups(14.9 +/- 2.3 versus 14.2 +/- 2.5 y/o ; P=NS), age of their mothers (38.8 +/- 5 versus 40.4 +/- 5.7 y/o; P=NS) and age of their fathers (44.5 +/- 5.8 versus 45.7 +/- 6 y/o; P=NS)(Table 1).In comparison of the CAD group and their matched control group ;the number of male subjects was much more than female ones in both groups (21 subjects or 70 % in CAD group and 18 ones or 60% in control group), but based on the Chi-Square test distribution of the variable ;gender, was equal in both above groups. (P=0.417=NS)

Cardiovascular Risk Factors

Biochemical tests characteristics in children of CAD history in parent control subjects are shown in (Table 2). FBS(91.4 +/- 7.9 versus 88.9 +/- 9.5 mg/dl ; P=NS), Total Cholesterol(162 +/- 29 versus 159 +/- 25 mg/dl ;PV=NS),LDL cholsterol (66.3 +/- 26 versus 70 +/- 28 mg/dl ; P=NS), and Triglyceride(117 +/- 55 versus 122 +/- 49 mg/dl ; P=NS), these amounts were not significantly different in the family history group and control group children.Four subjects in the case group were excluded because of hyperlipidemia. As shown in (Table 3) the amount of SBP(112 +/- 10 versus 112 +/- 12.3 ;P=NS),and DBP (66 +/- 8.5 versus 66 +/- 7.6 ;P=NS) in the family history and control group was the same.Two persons in the CAD group were submitted from the study since they had BP>130/85.

Brachial artery avaluation

Basal Brachial artery Diameter (BBD) in CAD subjects and control subjects offsprings was not different.(Table 3) Family history children,had markedly reduced Endothelium-Dependent Dilatation (EDD/BBD) (8.5 +/- 3.4% versus 11.8 +/- 4.5%, P =0.003); Endothelial Independent Dilation (EID/BBD) in the CAD group was significantly more than control subjects (family history, 18.5 +/- 6.7% and control subjects, 11.9 +/- 5.2%; P <0.001). EDD/EID or the index of endothelial function was significantly lower in the family history group(0.92 +/- 0.05 verssus 1+/- 0.03 in control subjects ;P<0.001)(Table 3). EDD / EID index was compared in two subgroups of family history subjects ; premature CAD in father and premature CAD in mother. Subjects with premature CAD in father had significantly impaired EDD/EID index in comparison to control group(0.91 +/- 5.5% versus 1+/- 0.03 in control subjects ; P<0.001) and those children whose mothers had premature CAD again EDD/EID index was markedly lower than control subjects(0.92 +/- 0.04 versus 1+/- 0.03 ; P< 0.001). ANOVA of these family history subgroups showed statistical significance (F = 26.12, P< 0.001),but in pairwise analysis EDD/EID index in groups of father with CAD and mother with CAD was not significantly different..

On Pearson Correlation analysis of the combined group of 30 family history subjects and control subjects, there was direct correlation between BBD and age (r = 0.63, P <0 .001), but EDD/EID was inversely related to age (r = - 0.21,P<0.05).

Discussion

This study showed that offsprings of premature CAD patents have endothelial dysfunction. Endothelial dysfunction means EDD/EID index less than one.The less

the EDD/EID index the more impairment of endothelial function .It showes that the amount of dilatation of artery in response to shear stress is lesser than it's dilatation in response to GTN. Endothelial dysfunction was obvious in subjects without additional risk factors except family history of premature CAD.There is no difference whether father has premature CAD or mother ,it means that if a man or a woman has premature CAD, his or her children are in risk of development of endothelial dysfunction and eventually establishment of CAD .

In a similar study in Australia by Clarkson PB, et al it has been shown that young adults with a family history of premature coronary disease have impaired endothelium-dependent dilatation.(17) Altough these results are the same as our study but their study was done in siblings of premature coronary disease patents,wheres this study was on children of these patints and showed that even one parent with premature coronary disease has some risk for his or her child to development of endothelial dysfunction and perhaps CAD in future .

In the Swedish study by Lind L,et al it was showed that apparently healthy subjects with a family history of myocardial infarction have impaired endothelial-dependent vasodilation in the forearm vasculature that was independent of traditional cardiovascular risk factors such as impairment in blood pressure, lipids, fasting blood glucose levels, smoking habits or intima-thickness of the carotid artery compared with those without the history of MI. (18).

In this study we excluded subjects with identifiable risk factors, ie, smoking, passive smoking, hypertension, diabetes, and dyslipidemia, because in previous studies, influence these cardiovascular risk factors on arterial function has been demonstrated . (17,20-22) . Most of mechanisms responsible for regulation of

vascular tone and function are unknown for us but one discovered is the role of renin-angiotensin-system. (23) There are many nonpharmacological and pharmacological interventions that improve or even normalize endothelial function in human:Low Cholesterol diet , fish oil consumption, smoking cessation, and exercise training are effective nonpharmacological interventions that their efficacy have proved in many trials.(24) Some pharmacological therapies are as followes : L-Arginine supplementation, lipid lowering agents especially statins,inhibitors of renin-angiotensin-aldosteron system such as ACE inhibitors(24),and calcium channel blockers like Amlodipine.(25)

When we identified those children with endothelial dysfunction, it suggests that they are at risk of CAD in future. By performing these interventions known as primary prevention we can be hopeful they will not at risk thereafter and it may reduce CAD incidence in future.We suggest: Endothelial function evaluation in offsprings of premature CAD parents and if it is abnormal perform interventions known as primary prevention for them.
